

Component Reliability After Long Term Storage

R. R. Madsen

ABSTRACT

Each year the semiconductor industry routes a significant volume of devices to recycling sites for no reliability or quality rationale beyond the fact that those devices were stored on a warehouse shelf for two years. This study identifies the key risks attributed to extended storage of devices in uncontrolled indoor environments and the risk mitigation required to permit safe shelf-life extension. Component reliability was evaluated after extended storage to assure component solderability, MSL stability and die surface integrity. Packing materials were evaluated for customer use parameters as well as structural integrity and ESD properties. Results show that current packaging material (mold compound and leadframe) is sufficiently robust to protect the active integrated circuits for many decades and permit standard reflow solder assembly beyond 15 years. Standard packing materials (bags, desiccant, and humidity cards) are robust for a 32 month storage period that can be extended by repacking with fresh materials. Packing materials designed for long term storage are effective for more than five years.

INTRODUCTION

This paper defines the risk factors associated with extended storage of plastic encapsulated integrated circuits in a warehouse (uncontrolled indoor environment) and the materials and practices required to assure the quality and reliability of the devices to the end user.

BACKGROUND

It is not uncommon in the electronics industry to specify a maximum time interval from device manufacture to shipment and receipt by the customer. The origins of date code age restrictions are not well documented, but it is probable that limitations of the packing materials for moisture sensitive components and post storage solderability of SnPb or Sn finishes contributed to the concerns of customers that led to the shelf life restrictions.

Prior to 1995, the U. S. Military specified electrical retest of devices if a 3 year date code window was exceeded. In 1995, the military specification that mandated electrical retest after 3 years was revised and that requirement was removed entirely. The military now prohibits date code restrictions on component orders.⁴

A comprehensive evaluation of Long Term Storage devices was started in 2004 by engineers in Dallas and Freising, utilizing both current devices and devices stored for >2 years in a warehouse environment. That study which included ATE re-verification of electrical performance, concluded that no reliability or quality issues would result from storage of devices well beyond a 5 year period.²

PROCEDURE

This study evaluated twenty devices packed in tubes or tape and reel that had been stored in a warehouse environment (<40°C and <90% RH) for periods of time ranging from two to seventeen years. The acronym LTS (Long Term Storage) is used to identify this aged material.

Packing materials were examined for signs of deterioration – this included tribocharging tests on clear tubes, black conductive tubes, and the cover tapes on T&R to evaluate the effectiveness of topical antistats. The “as opened” status of humidity indicator cards was noted and the cards were placed in a humidity monitored environment to test for functionality. Paper labels were examined for legibility and adhesion. Peel force testing was conducted on T&R. All packing materials were representative of the vendors and materials used at the time of manufacture.

The devices contained in the packing materials were carefully examined for signs of deterioration. Leads and pads of ten devices were examined microscopically and with SEM for any signs of corrosion or contamination. The surface areas of the leads were evaluated with EDS for any foreign material. Moisture/reflow testing verified MSL performance.

EXCLUSIONS

Devices with a NiPdAu lead finish were the primary focus in this evaluation. Other lead finishes exhibited satisfactory solderability after simulated LTS; however, this study did not include materials such as matte tin or solder bumps.

RISK ASSESSMENT

DEVICE SPECIFIC RISKS

Risk	Risk Mitigation
Device functionality and parametric performance after extended periods of shelf storage.	No failure mechanisms have been identified that would compromise the electrical performance or circuit reliability of LTS devices. HTOL and HTSL qualification data provides the best estimate of parametric performance over time. Devices are biased during HTOL testing – this is worst case compared to unbiased storage. FIT rates for Analog products have been in single digits for the past decade. This assures us that biased and unbiased devices would remain within data sheet limits far beyond the design life of the device.
Exposure to the ambient atmosphere for extended periods of time may oxidize the lead surface impacting solder wetting during assembly.	Aging studies have shown that NiPdAu lead finish devices pass solderability requirements beyond 8 years ¹ . Actual testing of LTS devices indicates that storage for 15 years does not compromise solderability ² .
Moisture absorbed in the epoxy matrix of devices categorized as MSL 2 to 6 could vaporize during reflow solder assembly and crack the package.	Devices targeted for LTS are packed in special metallized bags that are sealed with desiccant and a HIC. Moisture diffusivity of the MBB has been measured ³ and devices are transferred to new bags with fresh desiccant on a periodic basis.
Devices stored for extended periods may exhibit corrosion of bond pads or interconnect metallization.	Package qualifications include autoclave tests to evaluate the effect of moisture on die metallization (Galvanic corrosion). Devices routinely pass high temperature and humidity testing, which consists of 240 hours of autoclave at 121° and 100% RH which would translate to >7 years at 55°C and 60% RH and over 10 years at lower temperatures.
Devices that incorporate non-volatile memory may suffer data retention issues after long	Routine device qualifications include data retention tests performed at elevated temperatures. Existing data assures

Risk	Risk Mitigation
storage intervals.	us that biased and unbiased devices would maintain data integrity far beyond the design life of the device.

PACKING MATERIALS SPECIFIC RISKS

Risk	Risk Mitigation
<p>The static dissipative properties of tubes or tape and reel may degrade over time resulting in potential ESD damage to LTS devices.</p>	<p>Tubes: Tribocharge testing was conducted on LTS conductive and static dissipative tubes. Comparisons with fresh tubes from stock indicate device charge generation in aged tubes was comparable to new tubes.</p> <p>Tape and Reel: Static field meter data taken during detape operations indicate that no significant tribocharging occurs on LTS sample reels.</p> <p>Carrier tape pull testing indicated that the LTS reels require no special handling or adjustments to detape tooling during assembly.</p>
<p>Storage bags may leak, allow moisture to enter, and cause problems for MSL.</p>	<p>MBB: A breach of the MBB seal would be detected with a color change of the HIC and appropriate disposition of contained material.</p> <p>Extended storage bag manufacturer's data supports 5 year storage capability. Independent validation of Water Vapor Transmission Ratio (WVTR) for extended storage bags (5 years) was conducted at a contract lab⁵.</p>
<p>Label adhesives may fail or the ink marking could fade making lot history or device identification difficult.</p>	<p>Evaluation of material samples indicate no degradation in legibility or label adhesion after >17 years.</p>

SOLDERABILITY TEST

No indication of solderability degradation was observed in LTS or laboratory aged samples.

[Shelf-Life Evaluation of Lead-Free Component Finishes](#)¹
[TID – Old Datecode Study – 2007 \(Evaluation Work DW Package\)](#)²

MSL VERIFICATION TEST

LTS devices were evaluated with standard JEDEC MSL verification tests. Obviously, time zero data was not available for the retained samples; however, comparisons with MSL CSAM data for current devices in similar packages revealed comparable performance. No evidence of package cracks or other anomalies were observed in the test samples.

Figure 7 CSAM image of TPS2201 prior to moisture/reflow simulation. No significant delamination observed.

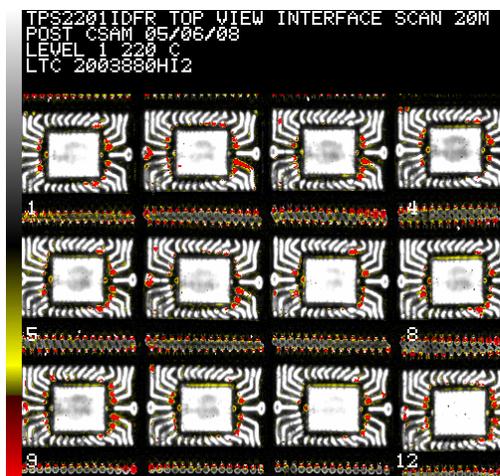

Figure 8 CSAM image of TPS2201 post Moisture/reflow simulation. Minor leadframe delamination observed.

EXAMINATION AND PHOTOGRAPHS OF PACKING MATERIALS

Devices were shipped directly to the evaluation lab with the existing packing materials and labels intact. The metallized heat sealed bags were opened and the contents photographed. Humidity Indicator Cards (HIC) were examined.

SUMMARY OF RESULTS

- No failure mechanisms have been identified that would compromise the reliability of plastic encapsulated ICs with NiPdAu lead finish stored for extended periods of time in a warehouse environment.
- Tribocharge voltages on LTS tape and reel samples during cover tape removal were comparable to current tape and reel samples.
- Tribocharge data from clear antistat tubes and black conductive tubes were compared to fresh tubes from stock. Charges measured on devices removed from the aged tubes were comparable to new tubes.
- Surface analysis of LTS leads revealed expected elements. SEM and optical microscopy revealed nothing abnormal. No degradation of the lead finish was observed.
- HIC color change with humidity was observed with all cards from the current qualified vendor.
- Solderability of LTS leads met all expectations and was indistinguishable from current devices.
- No degradation of MSL performance was observed.

CONCLUSION

The shelf life of LTS devices as determined by solderability, SEM visual, SEM spectral analysis, optical microscopy, MSL performance, solderability, and decapsulation/visual is >15 years.

IC packing material shelf life is limited by moisture diffusion through the MBB. A standard MBB maintains satisfactory moisture levels for 32 months. LTS bags control moisture levels beyond 5 years.

GLOSSARY OF TERMS

Desiccant: A hygroscopic substance used to remove moisture from moisture barrier bags.

Humidity Indicator Card: (HIC) – A card printed with a moisture sensitive chemical (cobalt chloride) that changes from blue to pink in the presence of water vapor.

Long Term Storage: (LTS) – Storage of devices in an uncontrolled indoor environment for more than two years.

Moisture Barrier Bag: (MBB) – Storage bag manufactured with a flexible laminated vapor barrier film that restricts transmission of water vapor.

Nickel, Palladium, Gold: (NiPdAu) – Metal layers that are pre-plated on leadframes to enable solderability.

Shelf Life: The time that moisture sensitive devices may be stored in MBB with desiccant and HIC or MSL 1 devices stored at room ambient.

Water Vapor Transmission Rate: (WVTR) – A measure of permeability of MBBs to water vapor.
